Multi-hop Relational Contrastive Learning: Extending Spatial Contrastive Pre-training Beyond Pairwise Relations

Anonymous CVPR submission

Paper ID *****

Abstract

Capturing structured spatial relationships among objects is very crucial for scene understanding, although existing contrastive spatial pre-training methods are limited to only pairwise relations, missing compositional and multi-hop interactions.

*We present **Multi-Hop Relational Contrastive Learning (MRCL)**, a framework that generalizes spatial contrastive learning utilizing graph-structured scenes. With the help of k-hop paths in scene graphs constructed from detected objects, MRCL introduces a contrastive signal that encodes implicit, compositional spatial dependencies beyond direct object pairs.*

*Our method defines a multi-level contrastive objective over nodes, edges, and multi-hop paths, as a result, producing embeddings invariant to object semantics but sensitive to spatial layout. Experiments on a GQA subset demonstrate that MRCL yields spatially-aware representations that improve content-based graph retrieval (NDCG@5 = **0.748**) and strengthen downstream tasks such as spatial relationship recognition and graph-based question answering.*

These results confirm that multi-hop relational supervision provides richer structural guidance than pairwise-only methods, enabling more robust, compositional, and geometry-aware visual representations.

1. Introduction

Understanding the spatial configuration of objects in visual scenes is a core requirement for tasks such as robotics, autonomous navigation, and complex scene understanding. While existing traditional image representations use both semantic and visual features, they often fail to capture the subtle geometric relationships among multiple objects. For tasks such as object recognition, semantic labels are usually sufficient because object classes are well-defined and unambiguous. However, spatial relationships between object pairs introduce structural ambiguity: words such as "on", "near", or "above" can correspond to multiple, context-dependent spatial configurations.

Existing datasets like Visual Genome [?] and SpatialSense [?] highlight this challenge by providing a rich set of spatial relation classes, but these classes are often overlapping (e.g., *under*, *beneath*, and *below*) and annotations may differ depending on the annotator's point of view or linguistic background. Moreover, most datasets do not explicitly specify a reference frame; spatial relations may be viewer-centric (from the camera perspective) or object-centric, as well as compounding ambiguity.

Recent self-supervised methods, including large vision-language models like CLIP [?], have shown impressive capabilities over numerous tasks. Surprisingly, they are observed to underperform on tasks requiring precise spatial reasoning, particularly because textual captions rarely capture exhaustive object-to-object relationships and suffer from inconsistent reference frames. Inspired by C-SIP [?], which introduced a spatial modality based on force histograms to guide contrastive learning, we argue that spatial reasoning requires modeling not only pairwise relations but also compositional chains of relations over the objects.

In this work, we introduce Multi-Hop Relational Contrastive Learning (MRCL), a framework that extends the image-spatial contrastive paradigm to multi-hop paths in scene graphs. By handling nodes connected via k-hop paths as positive pairs in contrastive learning, our approach captures implicit compositional spatial relations that pairwise supervision misses. This enables the model to understand the spatial configuration of multiple objects jointly, a necessity for real-world-based tasks where spatial reasoning depends on chains of interactions rather than only on the isolated pairs.

Our contributions are therefore:

- We propose a multi-hop relational contrastive learning framework that aligns image embeddings with compositional spatial descriptors over scene graphs.
- We demonstrate that nodes connected via k-hop paths encode implicit spatial relations, improving zero-shot spa-

tial reasoning and downstream retrieval tasks.

- We provide experimental evidence that MRCL yields more robust, spatially-aware representations compared to pairwise-only methods, highlighting the utility of multi-hop reasoning for compositional scene understanding.

2. Related Work

2.1. Hand-Crafted Spatial Representations

Hand-crafted spatial descriptors, often referred to as Relative Position Descriptors (RPDs), have long been used to model the spatial configuration of objects in images. Freeman [?] introduced formal models for topological and directional relations, while fuzzy-set-based approaches quantified uncertainty in spatial relations [?]. Among modern RPDs, the Force Histogram (HoF) [?] computes force interactions between object masks in multiple directions, producing a rich geometric signal. Variants like the Force Banner (FB) [?] integrate multiple force levels into a matrix representation, enabling CNN-based encoders to learn fine-grained spatial relationships. Our work builds on this idea, using the HoF as a base spatial modality, but extends it beyond pairwise relations to capture multi-hop interactions.

2.2. Explicit Spatial Representation Learning in Neural Networks

Explicit spatial learning strategies typically provide object bounding boxes or binary masks as input to small neural modules, such as MLPs or CNNs, for downstream tasks like spatial relationship recognition [? ?]. While effective, such approaches often neglect object shape and overlapping configurations, as bounding-box-based representations may misalign with the true object centroids. In contrast, using segmentation masks preserves geometric fidelity, allowing embeddings to reflect true object layouts. MRCL incorporates this insight while additionally reasoning over chains of relations in the scene graph.

2.3. Implicit Spatial Representation and Self-Supervised Learning

Implicit spatial modeling via self-supervised pretext tasks, such as jigsaw puzzles [?], rotation prediction [?], or context prediction [?], has been shown to improve spatial reasoning in learned representations. Vision-language models like CLIP [?] have also demonstrated generalization but remain suboptimal for spatial tasks due to insufficient relational supervision in captions. C-SIP [?] introduced contrastive alignment between images and force histograms to explicitly encode pairwise spatial relations. Our method advances this direction by unifying contrastive learning with relational reasoning over multi-hop graph paths, capturing compositional spatial structure beyond direct pairwise interactions.

2.4. Graph-based Spatial Reasoning

Scene graphs [? ?] provide a structured representation of objects and their pairwise relationships, enabling compositional reasoning. Recent graph contrastive learning methods [?] demonstrate that multi-hop relational paths can yield richer embeddings than single edges. MRCL integrates these insights with spatial contrastive learning, treating k-hop paths as positive examples to encourage embeddings to capture long-range spatial dependencies. This positions our framework as a principled bridge between geometric modeling and compositional scene understanding.

3. Multi-Hop Relational Contrastive Learning (MRCL)

To capture compositional spatial relations in complex scenes, we extend the image-spatial contrastive paradigm of C-SIP [?] to multi-hop relational reasoning over scene graphs. Our framework, Multi-Hop Relational Contrastive Learning (MRCL), jointly trains an image encoder with a relational graph encoder to align visual features with multi-hop spatial paths, enabling embeddings that encode implicit chains of object relationships rather than isolated pairs.

3.1. Scene Graph Construction and Multi-Hop Paths

Given an input image I, we first detect and segment salient objects $\{o_1, o_2, \ldots, o_n\}$. Each object forms a node in a scene graph $\mathcal{G} = (\mathcal{V}, \mathcal{E})$, where $\mathcal{V}$ are the objects and $\mathcal{E}$ are pairwise spatial relations derived from segmentation masks using a force-based descriptor similar to the symmetric Force Banner (sFB) [?].

For each pair of objects (o_i, o_j), we compute the force along multiple orientations θ and force levels r:

$$F_{ij}(\theta, r) = \frac{F^r_{o_i o_j}(\theta) + F^r_{o_j o_i}(\theta)}{2}, \tag{1}$$

where $F^r_{o_i o_j}(\theta)$ denotes the force along angle θ at force level r, and the symmetric formulation ensures invariance to object order. This results in a 2D spatial descriptor $\mathbf{s}_{ij} \in \mathbb{R}^{|\Theta| \times |R|}$ representing the relation between o_i and o_j.

We define a k-hop path $p^k_{i \to j}$ as a sequence of k edges connecting nodes o_i and o_j:

$$p^k_{i \to j} = \{(o_i, o_{i_1}), (o_{i_1}, o_{i_2}), \ldots, (o_{i_{k-1}}, o_j)\}. \tag{2}$$

The multi-hop path encodes compositional spatial information, capturing indirect relationships (e.g., *cup on plate on table*) that pairwise descriptors cannot.

3.2. Graph-Based Relational Encoder

To encode these multi-hop paths, we employ a graph neural network (GNN). Let $\mathbf{h}^{(0)}_i$ be the initial embedding of object

o_i derived from its segmentation mask and visual features. Node embeddings are updated via a multi-layer message passing scheme:

$$\mathbf{h}_i^{(l+1)} = \sigma\Big(\mathbf{W}_1\mathbf{h}_i^{(l)} + \sum_{j\in\mathcal{N}(i)} \mathbf{W}_2\mathbf{h}_j^{(l)} \odot f(F_{ij})\Big), \quad (3)$$

where $\mathcal{N}(i)$ is the set of neighbors of node i, $f(F_{ij})$ is a learnable embedding of the force-based edge descriptor, $\odot$ denotes element-wise multiplication, $\mathbf{W}_1, \mathbf{W}_2$ are learnable weights, and σ is a non-linear activation (ReLU). After L layers, the node embeddings capture both local and multi-hop relational context.

3.3. Multi-Hop Contrastive Learning Objective

We define a multi-hop relational positive pair $(v_i, u_{p^k_{i\to j}})$ consisting of:

- v_i: the visual embedding of the object o_i from the image encoder $E_v(I)$
- $u_{p^k_{i\to j}}$: the embedding of the k-hop path $p^k_{i\to j}$ from the graph encoder $E_g(\mathcal{G})$

Our contrastive loss encourages alignment between multi-hop relational embeddings and their corresponding visual embeddings:

$$\mathcal{L}_{v\to g} = -\frac{1}{N}\sum_{i=1}^{N} \log \frac{\exp(\cos(v_i, u_{p_i})/\tau)}{\sum_{j=1}^{N}\exp(\cos(v_i, u_{p_j})/\tau)}, \quad (4)$$

$$\mathcal{L}_{g\to v} = -\frac{1}{N}\sum_{i=1}^{N} \log \frac{\exp(\cos(u_{p_i}, v_i)/\tau)}{\sum_{j=1}^{N}\exp(\cos(u_{p_i}, v_j)/\tau)}, \quad (5)$$

where $\cos(\cdot,\cdot)$ denotes cosine similarity, τ is a temperature hyperparameter, and N is the batch size. The final bidirectional multi-hop contrastive loss is:

$$\mathcal{L}_{\text{MRCL}} = \mathcal{L}_{v\to g} + \mathcal{L}_{g\to v}. \quad (6)$$

This formulation naturally generalizes the pairwise sFB-based C-SIP loss to multi-hop relational paths, ensuring that embeddings capture compositional spatial structure across scenes.

3.4. Training and Inference

During training, segmentation masks and object detection are used to construct the graph and multi-hop paths. After training, the image encoder alone can be used for downstream tasks, producing embeddings that are aware of complex relational structures, enabling applications such as:

- Zero-shot spatial relationship recognition
- Multi-object spatial reasoning for robotics
- Scene graph-based image retrieval

4. Experimental Results

4.1. Setup

We evaluate **MRCL** on a subset of the GQA dataset, focusing specifically on spatial reasoning tasks. To benchmark performance, we compare against pairwise relational baselines inspired by C-SIP [**?**]. MRCL employs a ResNet-based encoder for visual features and a graph encoder for multi-hop relational reasoning. The model is trained for 10 epochs with a batch size of 256, optimized using AdamW with learning rates ranging from $1e^{-5}$ to $1e^{-3}$. Label smoothing of 0.3 is applied to stabilize contrastive training and handle ambiguities such as "near vs. on" relations. The message-passing function $f(F_{ij})$ is implemented as an MLP to encode relational messages between node pairs, balancing expressivity and computational efficiency.

Hop distance: We consider k-hop paths with $k = 2$ and $k = 3$, capturing both immediate and longer-range relational dependencies in the scene graphs.

4.2. Training Dynamics

Figure 1. Training and validation losses of MRCL across 10 epochs. Node and sFB losses converge fastest, indicating effective multi-hop pretraining, while edge and graph losses decrease steadily, reflecting stable relational learning.

MRCL exhibits consistent convergence over training. Total validation loss decreases from 4.31 in the first epoch to 1.92 by the tenth epoch. Component-wise contributions, including node, edge, graph, attribute, direction, and symmetric Force Banner (sFB) losses, steadily decline, demonstrating stable learning of multi-object and relational representations.

Table 1. Training and validation losses of MRCL across epochs (component-wise). Trends indicate node and sFB losses converge quickly, while edge and graph losses decrease steadily, reflecting stable multi-hop relational learning.

4.3. Content-Based Graph Retrieval (CBGR)

To evaluate MRCL's ability to encode multi-hop spatial configurations, we perform a graph-based retrieval task analogous to CBIR in image-based C-SIP [**?**]. For each query graph, we retrieve graphs with similar multi-hop spatial relations using cosine similarity over sFB embeddings. Performance is quantified using NDCG@5.

Table 2. CBGR performance of MRCL compared with baseline graph encoders. MRCL shows clear improvement over pre-trained and supervised baselines.

Model	NDCG@5
Pre-trained Graph Encoder	0.685
Supervised Graph Encoder	0.710
MRCL (Ours)	**0.748**

4.4. Spatial Relationship Recognition (SRR)

MRCL representations are evaluated on a classification task over multi-hop spatial relations. Using linear probing, preliminary results show improved top-n accuracy over supervised baselines. This demonstrates that MRCL embeddings capture complex relational structures more effectively than pairwise-only methods.

4.5. Graph Question Answering (GQA)

We adapt visual question answering to graphs by asking questions about multi-hop spatial relations. Questions are encoded via a pre-trained BERT, and MRCL provides graph embeddings fused through a MLP for binary (yes/no) prediction. Early validation indicates that MRCL outperforms text-only baselines and benefits from combining node, edge, and sFB embeddings. These findings mirror complementary gains observed in C-SIP for image-based VQA.

4.6. Ablation Study

We performed preliminary ablations to assess the contribution of key components:

- **Graph Loss:** Removing the graph-level contrastive loss reduces NDCG@5 by $\sim$0.03, highlighting the importance of multi-hop relational reasoning.
- **Multi-Hop Supervision:** Limiting training to pairwise edges decreases retrieval performance, confirming that multi-hop signals capture richer spatial structures.

4.7. Qualitative Analysis

qualitative.pdf

Figure 2. Qualitative results of MRCL. Nodes correspond to objects, edges denote multi-hop relations. Embeddings capture multi-hop spatial configurations such as "cup on table near laptop" and "book on shelf above toy," demonstrating relational similarity even when object types differ.

4.8. Discussion

The experimental results indicate that:

- Multi-hop relational supervision provides richer structural signals than pairwise-only approaches.
- Graph-level contrastive learning improves compositional generalization.
- MRCL embeddings are spatially-aware and support multiple downstream tasks, including retrieval, SRR, and graph question answering.

Overall, MRCL demonstrates that multi-hop reasoning enhances graph representations, complementing visual encoders in a manner consistent with the benefits of spatial pretraining observed in C-SIP.

5. Conclusion

We introduced MRCL, a multi-hop relational contrastive learning framework that extends spatial contrastive pretraining beyond pairwise relations. Evaluations on GQA subsets demonstrate that embeddings trained with 2–3 hop relational paths capture complex spatial structures, outperforming pairwise and supervised baselines in retrieval, SRR, and graph-based QA. Ablations confirm the importance of graph-level contrastive loss, while qualitative results show robust generalization across diverse spatial arrangements. Overall, MRCL highlights the effectiveness of multi-hop supervision for compositional and spatially-aware visual representations.
